

Systemic risk in energy derivative markets: a graph-theory analysis

D. Lautier & F. Raynaud

University Paris-Dauphine

Ecole Polytechnique Fédérale de
Lausanne

Objectives

- Empirical study on systemic risk in derivative markets
- Approach in three dimensions
 - Observation time
 - Spatial integration
 - Maturity of the transactions
- Influence of physical as well as derivative markets
- Integration as a necessary condition for systemic risk to appear
- Correlations, co-movements

Selected markets

- Choice directed by:
 - Concerns about speculation in commodities
 - Energy products
 - Development of bio fuels
 - Agricultural products
 - Portfolio management / Commodities as a new class of assets
 - Financial instruments
 - Organized markets with the highest transaction volumes
- 14 markets (> 760 000 daily futures prices (settlement))
- 1998 - 2011

Methodology

- Huge volume of data + 3 dimensional analysis
- Price system = complex evolving system
- Use of methods originated from statistical physics
- Graph-theory and networks
- Graph :
 - Nodes : time series of daily futures returns
 - Links : correlations between the price returns
- Full connected graph :
all possible connections between N nodes (time series of price returns) with $(N(N-1)/2)$ links

Example of the crude oil market (1 market, maturity dimension)

Methodology

- Information in the graph is filtered
 - most relevant links
 - highest correlations
- Minimum Spanning Trees (MST)

Mantegna (1999)

Path for the propagation of prices fluctuations

1. How did we get minimum spanning trees?
2. Our results with the MST, in the 3 dimensions :
maturity, space, 3D
3. Dynamical analysis on the graphs and on the MST

1. Minimum spanning trees

- Synchronous correlation coefficients ρ of prices returns r :

$$r_i = \frac{(\ln F_i(t) - \ln F_i(t - \Delta t))}{\Delta t}$$

$$\rho_{ij}(t) = \frac{\langle r_i r_j \rangle - \langle r_i \rangle \langle r_j \rangle}{\sqrt{(\langle r_i^2 \rangle - \langle r_i \rangle^2)(\langle r_j^2 \rangle - \langle r_j \rangle^2)}}$$

- With: $F(t)$, futures prices at t
- Correlation matrix C , (NxN), symmetric

From correlations to distances

- Non linear transformation
- Distances d between two nodes defined as follows:

$$d_{ij} = \sqrt{2(1 - \rho_{ij})}$$

- Distance matrix D , (NxN)
- Full connected graph
 - represents all the possible connections between N nodes
 - weighted by the distances

Minimum spanning tree

- All the nodes of the graph are spanned
- No loops
- Result: links of the MST are a subset of the initial graph
- The information space is reduced from $(N(N-1)/2)$ to $(N-1)$
- In this study : shortest path linking all nodes

Easiest path for the transmission of prices shocks

2. Topology of the MST

Star-like tree

Chain-like tree

2. Topology of the MST

2.1. Maturity dimension

2.4 Allometric coefficients

- Quantifying the degree of linearity in the trees
- The root is the node with the highest connectivity
- Starting from this root, two coefficients A_i and B_i are assigned to each node i :

$$A_i = \sum_j A_j + 1$$

$$B_i = \sum_j B_j + A_i$$

$$B \sim A^\eta$$

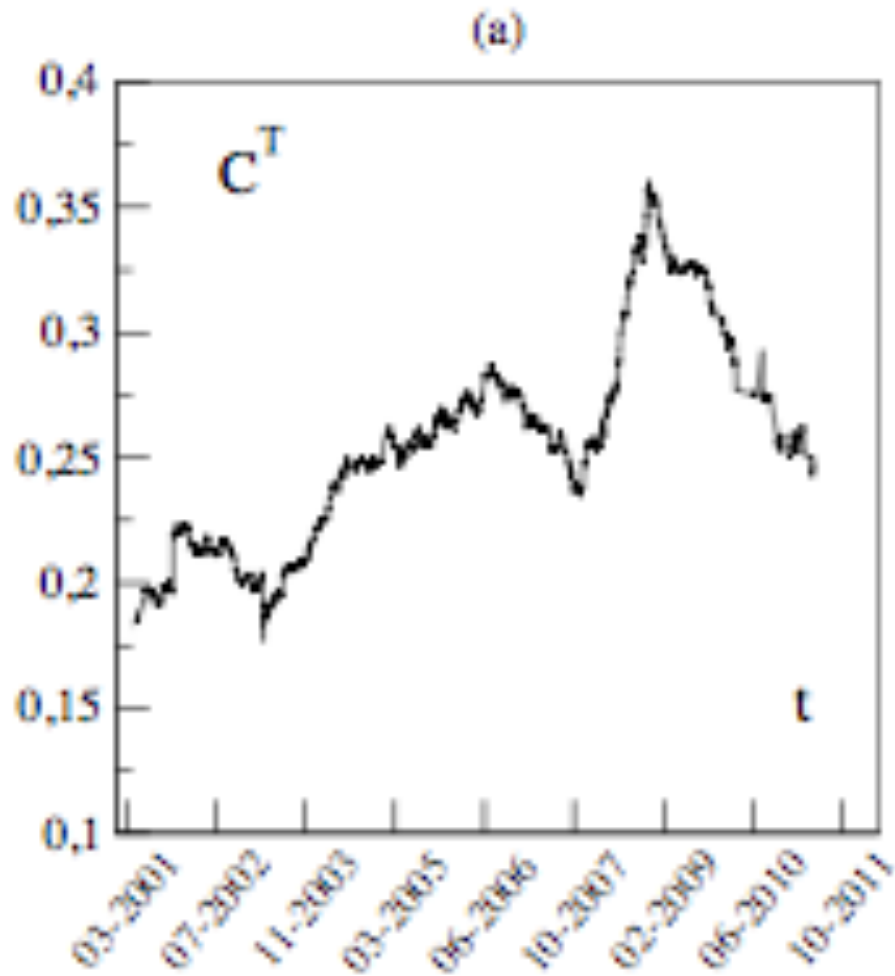

Where η is the allometric exponent
 η stands between 1+ (star-like) and 2- (chain-like)

MATURITIES	Static	CI95%	Dynamic	CI95%
Light crude	1.994	1.9058 – 2.0822	1.910	1.8904 – 1.929

3. Dynamical studies

3.1. Full connected graph : mean correlations and their variances (3-D)

3.2. Node's strength

- Full connected graph
- The node's strength S_i indicates the closeness of one node i to all others:

$$S_i = \sum_{i \neq j} \frac{1}{d_{ij}}$$

Energy

(a)

(b)

(c)

(d)

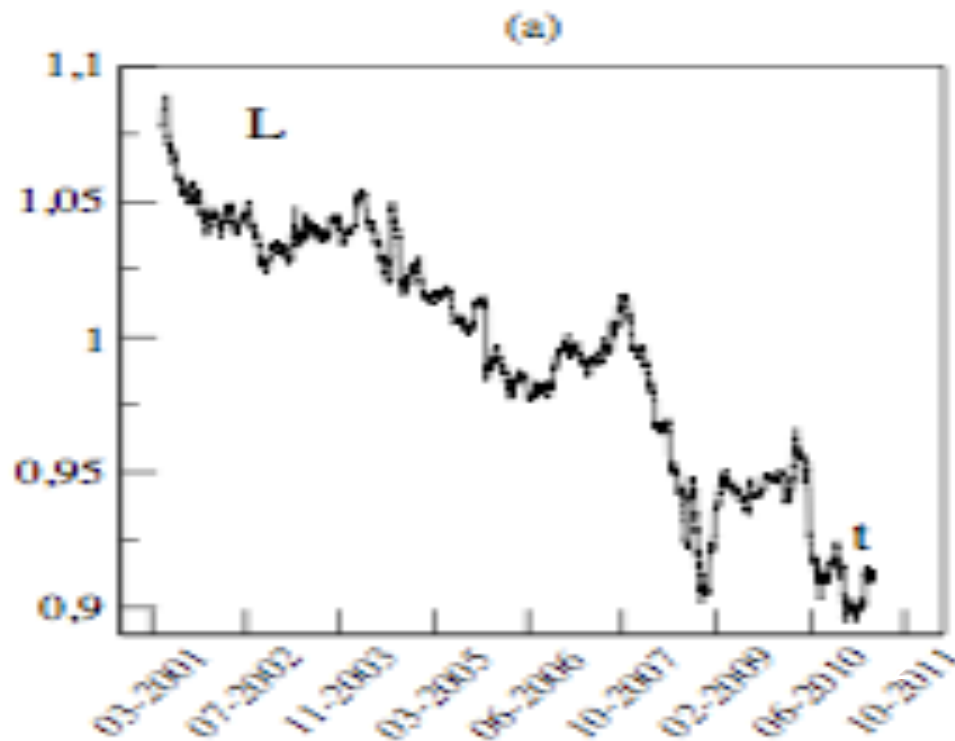

3.3. Normalized tree's length

- Sum of the lengths of the links belonging to the MST:

$$L(t) = \frac{1}{N-1} \sum_{(i,j) \in MST} d_{ij}$$

- The more the length shortens, the more integrated the system is

Spatial
dimension

3.4. Survival ratios

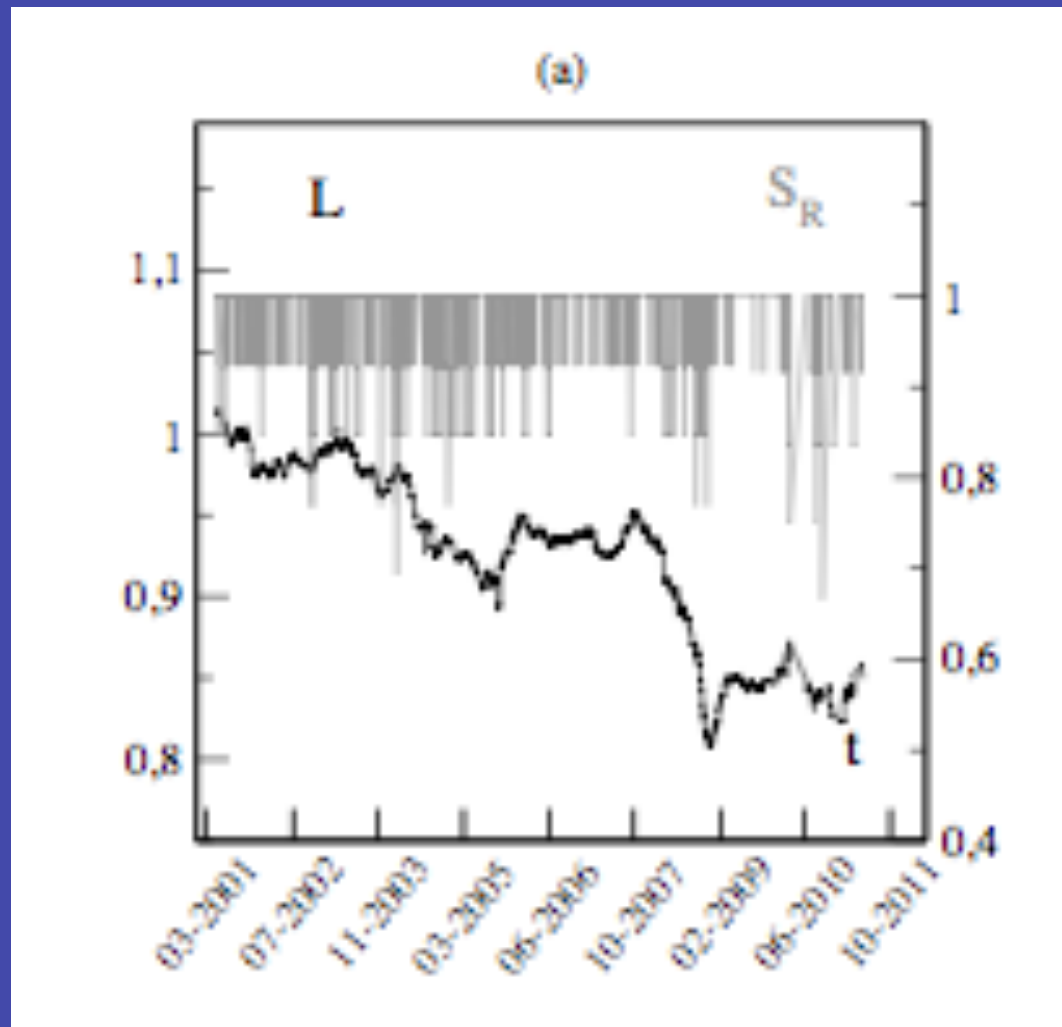

- Robustness of the topology over time
- The survival ratio S_R refers to the fractions of edges in the MST, that survives between two consecutive trading days:

$$S_R(t) = \frac{1}{N-1} |E(t) \cap E(t-1)|$$

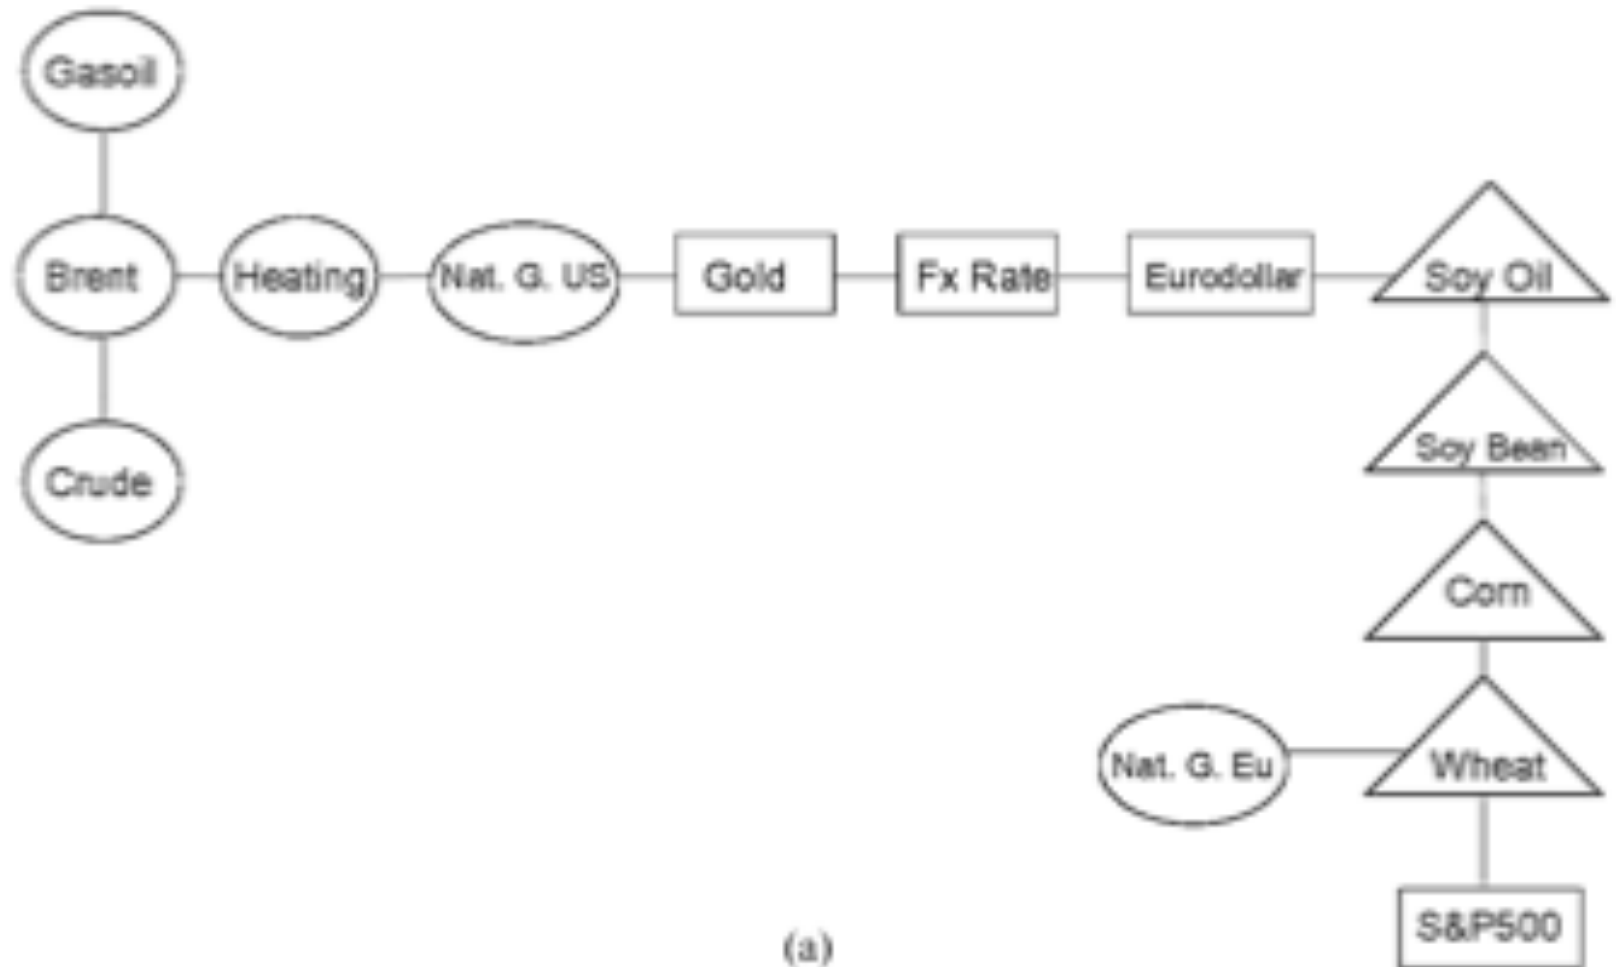

$E(t)$: set of edges at t

Pruning the trees

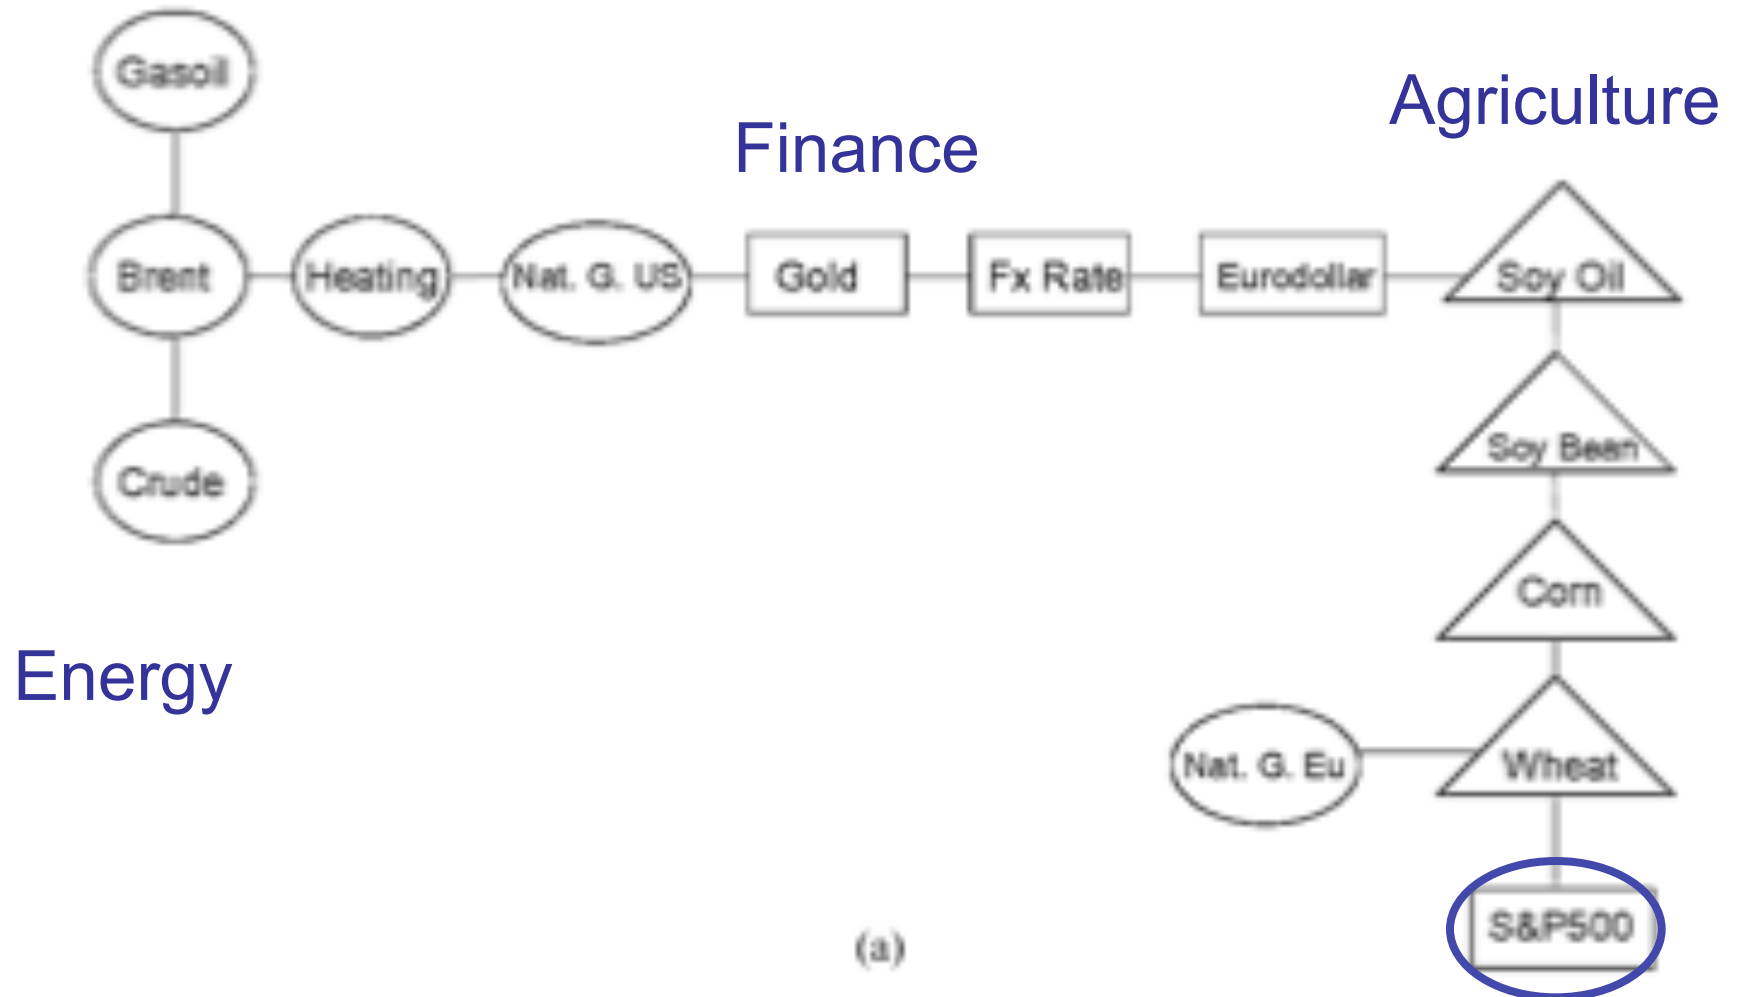

- Analysis of inter-market and inter-sectors reorganizations
- Consider only the links between markets, whatever the maturity is considered

Pathological configuration : an example

Pathological configuration : an example

Most stable links

Main results - Extensions

MAIN RESULTS

1. Topology

- Chain-like trees in the maturity dimension
- Star-like trees in the spatial and 3-D dimensions

2. Emerging taxonomy

- Trees organized around the three sectors of activity
- Center of the graph : two crude oils

3. Integration

- Increases in all dimensions (spatial, maturity, 3D)
- Progresses at the heart of the system

EXTENSIONS

1. Introducing directions in the graph
2. Event studies / financial crises

1. Introducing directions in the graph

- Full connected graph
- Information flows :
 - static analysis
 - dynamic analysis

Full connected graph, maturity dimension

Information flows: static analysis
